Abstract.

Spanish astronomy has grown rapidly during the 1990s. The number of papers published per year has doubled, to about 4% of the world total. The number of high-impact papers, however, remains constant at about 1% of the world total. Papers from France, Germany and Italy also have lower impact than their numbers suggest, while for the US, UK, Japan, Netherlands and Australia, the fraction of high-impact papers is approximately the same as the fraction of all papers. We suggest a few possible explanations for this difference.

1. Introduction

Professional astrophysics has a short tradition in Spain compared with other European countries. However, the inauguration of two world-class observatories (La Palma, Calar Alto) in Spain in the 1980s has allowed Spanish astronomy to develop rapidly in recent years, with a large increase in the number of astronomers, in the number of institutions, in public interest, and in funding.

We have made a quantitative study of the productivity of Spanish astronomy during the 1990s, in order to compare its standing with that of astronomy in other countries.

2. Growth of Spanish astronomy

The number of papers published per year per astronomer is shown in Fig. 1a for the two largest Spanish astronomical institutions (IAC and IAA, which include 50% of all Spanish astronomers), and examples of two small

Figure 1. Growth of Spanish astronomy in the 1990s. (a) Number of papers published per astronomer in different Spanish institutions: IAC (solid circles), IAA (squares), OAN (crosses) and IFCA (stars). The solid line is the best-fit straight line. (b) Fraction of astronomical papers published worldwide which originated in Spain.

institutions, one old (OAN, founded 1790, with 15 astronomers in 1998), and one new (IFCA, founded 1994, with 12 astronomers in 1998). The data are taken from lists of publications provided by the institutions themselves. Fig. 1a shows that there are no significant differences between the productivities of astronomers at the different institutions, and that the number of papers per astronomer has risen by a factor of two between 1989 and 1998. The number of Spanish astronomers as a function of time was deduced from a variety of published statistics, including IAU membership figures for 1993 and 1998. The ratio between number of astronomers and gross domestic product (GDP) is now similar to that for most other countries active in astrophysics. Combining the estimates of the number of papers per astronomer with the number of astronomers yields, as a function of time, the estimated fraction of all astronomy papers worldwide published from Spain (Fig. 1b). Our estimates of the Spanish fraction are similar to those given on the ISI web pages. This growth over the last decade is larger than for any of the other top 15 countries active in astrophysics.

3. Impact of Spanish astronomy

As metrics of scientific productivity and impact, we counted for each country:

Figure 2. Scientific impact vs number of papers for different countries. Both parameters are given as a fraction of the world total. 'Scientific impact' is an average of two measures, one based on the number of citations to the top-1000 most-cited papers, one on the number of papers published in Nature. The solid line indicates % impact = % papers. The dotted lines indicate 1, 3 and 5 σ departures from the solid line.

1. The number of papers published in refereed journals 1994-99 (data taken from the web page of ISI, the Institute of Scientific Information).
2. The number of citations to papers amongst the top-1000 most-cited worldwide, published during 1991-98.
3. The number of observational papers published in Nature during 1989-98 (from a total of 453). Nature has an impact factor (citations per paper) 8 times larger than any astronomical journal.

For each of the above counts, each paper was assigned to the country hosting the first author. Full details of the second and third datasets above, and a discussion of possible biases, are given by Benn & Sánchez(2000) and Sánchez & Benn(2000).

Number of papers published (the first metric) is often used as a measure of scientific productivity, but may not reliably reflect scientific impact (the last two metrics). The average of the last two metrics is compared with the first, in Fig. 2, for 9 countries for which data on all 3 metrics were available. For 5 of the countries (the US, UK, Japan, Netherlands and Australia), the two fractions are similar. For Germany, France, Italy and Spain, the ratio between impact and total number of publications is a factor of ~ 2.5 lower. There are several possible explanations for the lower fraction of high-impact papers in these countries. One is language bias (which can affect citation rates in a number of ways); in 4 of the 5 countries in the former group,

most scientific discourse and publication takes place in English. Another possibility is that the level of resources provided affects the fraction of high-quality papers. In Spain and Italy, $\sim 1\%$ of the GDP is spent on research; in most other countries (but including France and Germany), the fraction is $\sim 2\%$. A further possibility, highlighted by Nature (1998), is that the academic environment in the former group of countries is more competitive, with most research done in universities rather than dedicated institutions, and with more open competition for posts (see Nature 1998 for discussion of the latter in Spain).

4. Conclusions

Spanish astronomy is a young science. The number of professional astronomers, number of papers per astronomer and fraction of papers (compared with the other countries) have all risen by a factor ~ 2 in the last decade. The fraction of Spanish astronomical papers has risen from $\sim 2\%$ in 1989 a $\sim 4\%$ in 1998. However, the fraction of high-impact work has remained constant at $\sim 1\%$ during this period. For Spain (and for France, Germany and Italy) the ratio between the number of high-impact papers, and the total number of papers published, is lower than for the US, UK, Japan, Netherlands and Australia. Possible reasons are language bias, smaller research budgets, or less competitive deployment of research resources.
